# A New Multiphase CFD Erosion Model for Predicting Material Erosion from Sand Slurries

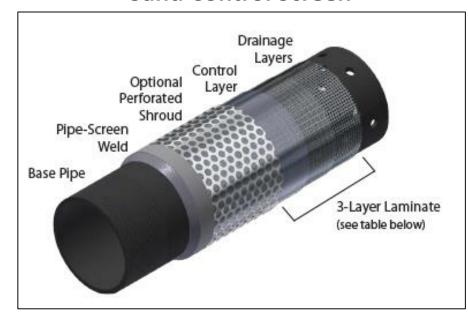

NETL 2021 Virtual Workshop on Multiphase Flow Science

Amy B. McCleney, Ph.D.
Senior Research Engineer
Southwest Research Institute (SwRI)
Amy.mccleney@swri.org

## Dynamic process that causes material removal from a target surface due to impingement of fast-moving solid particles

#### **Sand Control Screen**

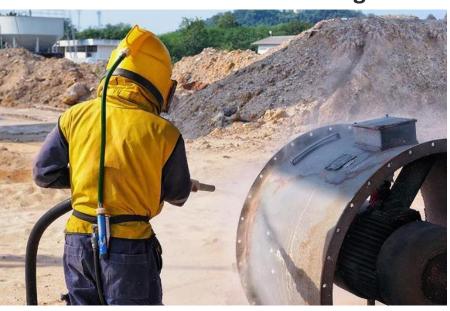

(Porous Metal Filters 2021)

Vehicle Operating in a Desert Environment

(Friedrich 2015)

**Powder Abrasive Cleaning** 

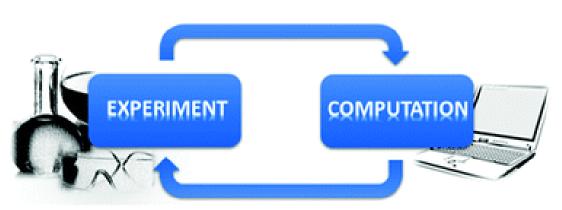

(Chemours 2020)

## **Erosion Prediction**

- Can typically be accomplished either through testing programs or with computational fluid dynamics (CFD) multiphase modeling efforts
- Testing can generally be:
  - expensive
  - time-consuming
  - limited in terms of conditions that the facility can handle
- Computational modeling of erosion is a low-cost alternative to testing for preliminary design analysis, but models:
  - are semi-empirical
  - have a low degree of accuracy

## **Computational Erosion Prediction**

#### **Parameters Selected for Particle Erosion Models**

A review of 28 different erosion models provided 33 different input parameters

On average only 5 parameters are used per model

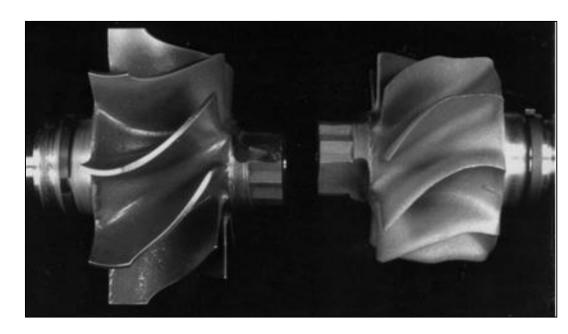

| Parameters Selected for Particle Erosion Models |                               |  |  |  |  |  |  |
|---|-------------------------------|--|--|--|--|--|--|
| Erodent   | Target                        | Fluid Flow                                       |  |  |  |  |  |

- 96-hour test duration
- Test samples pulled approximately
   24 intervals
- Particle size distribution measurement
- High-resolution images of particles and coupons

#### **Silicon Carbide Particles**

#### **Eroded 316 Stainless Steel**

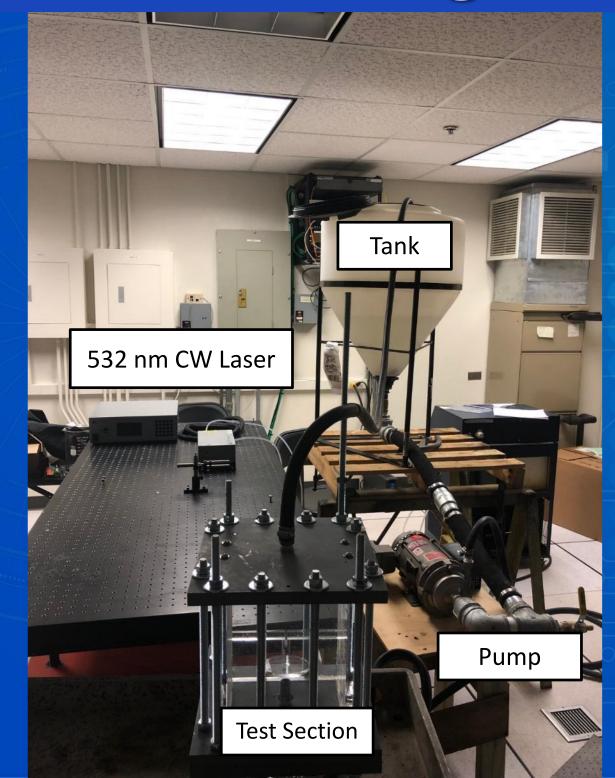

## PIV Test Configuration

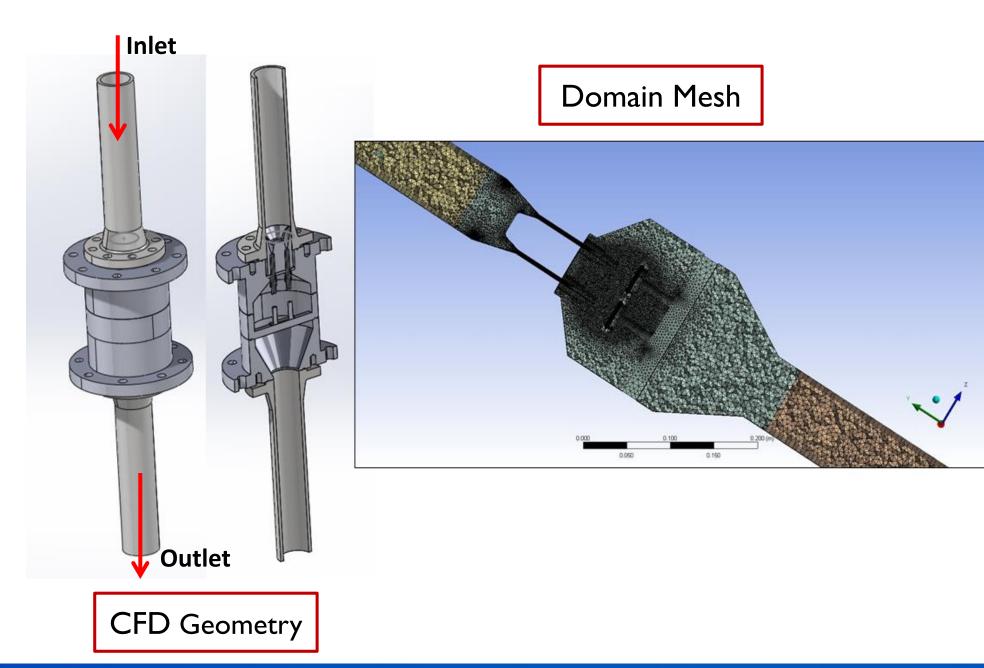

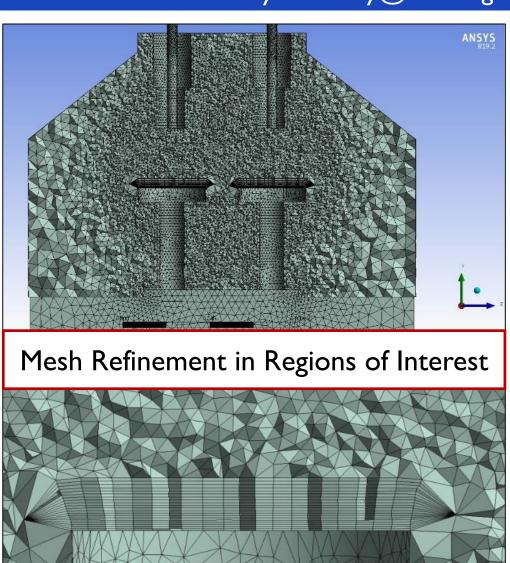

- P-cymene
- 4.5 Watts
- 200 mm macro lens
- 2000 fps
- 0.2 ms exposure
- 1024 x 1024 resolution
- I.5 GPM

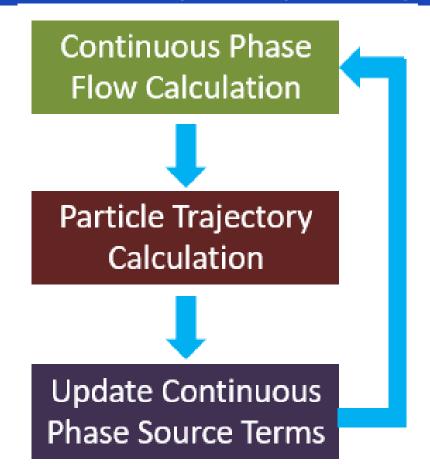

MECHANICAL ENGINEERING

## CFD Approach

- Analysis conducted in ANSYS<sup>®</sup> Fluent<sup>®</sup>
- Eulerian-Lagrangian approach
- Using discrete phase modeling (DPM)
- Stochastic tracking
- C-based user-defined macro analyzed localized erosion rates (kg/m²-s) at wall boundaries of interest

#### **Multiphase Model Integration**

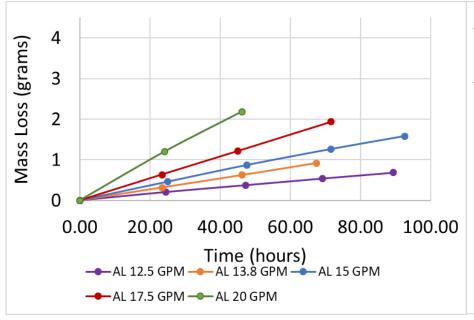

- I. Single-phase model only
- 2. Discrete phase model (DPM) with constant-sized particles
- 3. DPM with particle size distribution
- 4. Review default erosion models
- 5. Integrate SwRI erosion model

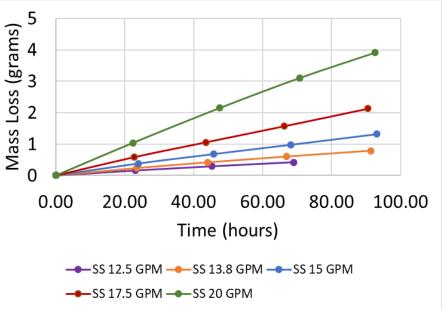

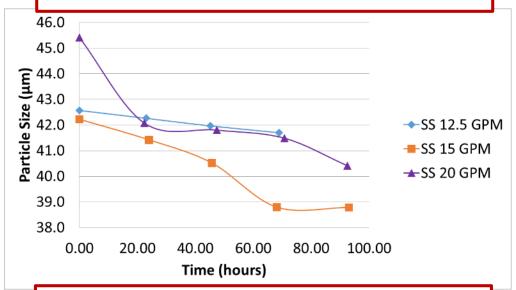

## **Experimental Program Results**

### **New Erosion Model**

#### Equation takes the following form:

$$SE = Kv^n D_p^x B^y f(\alpha) C_0$$

$$SE = \frac{ER_{erosion}A_{face}}{\dot{m}_p}$$

- SE = specific erosion (unitless)
- *K* = constant coefficient (unitless)
- V = velocity (m/s)
- $D_p$  = particle size (µm)
- B = Brinell hardness = SI form (unitless)
- $f(\alpha)$  = impact angle function (degrees)
- $\alpha$  = impact angle (degrees)
- $C_0$  = concentration (ppm)
- n, x, y = constants (unitless)
- $ER_{erosion}$  = erosion rate (kg/m<sup>2</sup>-s)
- $A_{face}$  = surface area of the impacted wall (m<sup>2</sup>)
- $\dot{m}_p$  = mass flow rate of the impacting stream of particles (kg/s)

**New Model:** 

$$SE = 2.3 \times 10^{-17} (0.9978 v - 0.0016)^{2.708} D_p^{1.093} B^{-0.379} f(\alpha) C_0$$

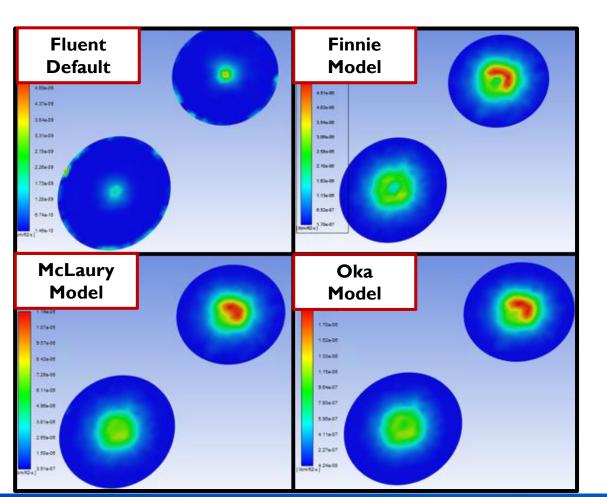

$$f(\alpha) = 9.37\alpha - 42.295\alpha^2 + 110.864\alpha^3 - 175.804\alpha^4 + 170.137\alpha^5 - 98.398\alpha^6 + 31.211\alpha^7 - 4.11\alpha^8$$

For 
$$C_0 < 1,570 \ ppm$$

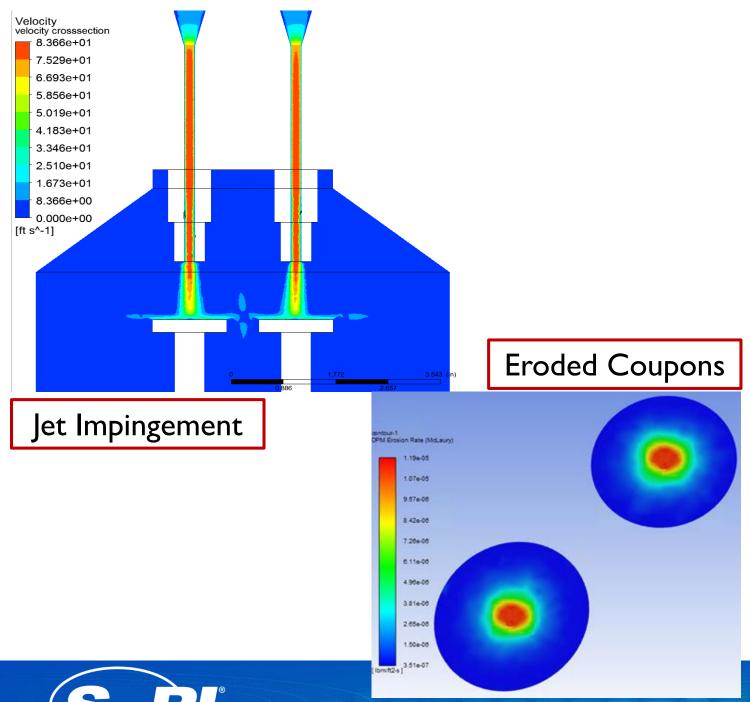

$$C_0 = 9 \times 10^{-16} C - 5 \times 10^{-13}$$

For  $C_0 \ge 1,570 \ ppm$ 

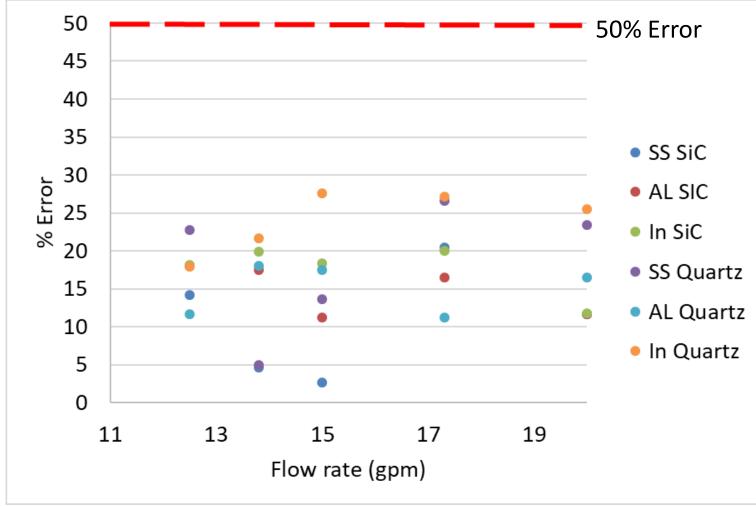

$$C_0 = 8 \times 10^{-16} C - 2 \times 10^{-13}$$

| Erosion Model  | Minimum<br>Erosion Rate<br>(lbm/ft <sup>2</sup> -s) | Maximum<br>Erosion Rate<br>(lbm/ft <sup>2</sup> -s) | Average<br>Erosion Rate<br>(lbm/ft <sup>2</sup> -s) | Percent Difference from Experimental Results |
|----------------|---|---|---|--|
| Experimental   |   |   | 3.10 × 10 <sup>-7</sup>                             |  |

#### Comparison to Validation Data

## Summary and Next Steps

- Validation testing program undertaken to help improve erosion prediction computationally
- Large dataset collected, which helps generate empirical correlations that were integrated into the CFD software to calculate localized erosion rates
- New model demonstrated a 28% agreement with validation data, showing an 25× improvement over commercial software

Currently validating model accuracy on complex geometries
